(54) **Gas phase catalytic process for production of vinylidene fluoride.**

(57) Vinylidene fluoride is produced from the catalytic, gas phase reaction of hydrogen fluoride and at least one halohydrocarbon of the formula  $\text{CH}_n\text{CX}_m$  wherein n and m are 2 or 3 and each X is independently selected from the group of fluorine, chlorine, bromine and iodine, provided each X is not simultaneously fluorine. 1,1,1-Trifluoroethane, added to the vapor phase reaction mixture as a diluent, improves the performance of the fluorination catalyst, increasing selectivity for the desired product, vinylidene fluoride.

## GAS PHASE CATALYTIC PROCESS FOR PRODUCTION OF VINYLIDENE FLUORIDE

### Field Of The Invention

The invention relates to the production of vinylidene fluoride. More particularly, the invention relates to a gas phase catalytic process for the hydrofluorination of 1,1,1-trichloroethane and/or vinylidene chloride to produce vinylidene fluoride.

### Background Of The Invention

1,1,1-Trifluoroethane is a waste by-product. It may be recovered and dehydrofluorinated to form vinylidene fluoride. See Japanese Published Patent Application 54/130507. Alternatively, the 1,1,1-trifluoroethane is incinerated.

While the dehydrofluorination of 1,1,1-trifluoroethane to generate vinylidene fluoride is feasible, other uses of 1,1,1-trifluoroethane are sought.

It has not been heretofore recognized that hydrofluorocarbons may be utilized as diluents and catalyst activators to improve the performance of gas phase fluorination catalysts, in particular catalysts utilized in the hydrofluorination of 1,1,1-trichloroethane or vinylidene chloride.

### Summary of The Invention

A process for producing vinylidene fluoride is provided. A vapor phase reaction mixture is formed comprising hydrogen fluoride and at least one halohydrocarbon of the formula  $\text{CH}_n\text{CX}_m$  wherein n and m are 2 or 3 and each X is independently selected from the group of fluorine, chlorine, bromine and iodine. 1,1,1-Trifluoroethane is added to the vapor phase mixture as a diluent, and hydrogen fluoride and the halohydrocarbon react in the presence of a heterogeneous fluorination catalyst. Vinylidene fluoride is obtained as a reaction product. Preferably, the 1,1,1-trifluoroethane added to the reaction mixture comprises a hydrofluorination reaction by-product which is separated from vinylidene fluoride and recycled back to the reaction mixture.

According to one embodiment of the invention, a continuous process for the production of vinylidene fluoride is provided. At least one halohydrocarbon as defined above is continuously fed to a reaction zone. Hydrogen fluoride and the halohydrocarbon are continuously reacted in the

vapor phase in the reaction zone in the presence of a heterogeneous fluorination catalyst. A product mixture comprising vinylidene fluoride and 1,1,1-trifluoroethane is continuously withdrawn from the reaction zone, and at least a portion of the 1,1,1-trifluoroethane is recycled back to the reaction zone.

### Detailed Description of the Invention

We have found that 1,1,1-trifluoroethane, heretofore regarded as a waste by-product in the gas phase catalytic hydrofluorination of  $\text{CH}_n\text{CX}_m$  halohydrocarbons, may be utilized as a diluent and catalyst activator to improve the selectivity for the desired product, vinylidene fluoride, in the hydrofluorination reaction. Thus, it is believed that the addition of 1,1,1-trifluoroethane back to the reaction mixture improves the performance of the heterogeneous hydrofluorination catalyst. According to the present invention, the selectivity for vinylidene fluoride may be increased by 10-15%, depending on the operating conditions.

Generally, hydrogen fluoride and the  $\text{CH}_n\text{CX}_m$  halohydrocarbon are fed to the reaction zone at a molar ratio of from about 0:1 to about 10:1, preferably from about 1:1 to about 4:1. The feed of hydrogen fluoride may be reduced to zero in some circumstances by virtue of the in situ generation of hydrogen fluoride by the dehydrofluorination of 1,1,1-trifluoroethane, which proceeds simultaneously with the hydrofluorination of the  $\text{CH}_n\text{CX}_m$  halohydrocarbon. The reactants are combined in a reaction zone in the gaseous state. The reaction zone may comprise any of the known reactor vessels suitable for gas phase hydrofluorination. Such devices are well known to those skilled in the art.

The process may be operated at any temperature favoring the conversion of the halohydrocarbon to vinylidene fluoride. Generally, the process is operated at a temperature of from about 400°C to about 650°C, preferably from about 550°C to about 625°C. The pressure is not critical, provided it is not so great that the reactants would be liquified at the reaction temperature.

The residence time of the reaction mixture in the reaction zone at the reaction temperature may be selected in accordance with the desired extent of conversion of halohydrocarbon to vinylidene fluoride. Typically, the reactants are in contact in the reaction zone for a period of time from about 1 second to about 20 seconds, preferably from about 5 to about 20 seconds.

The feed may comprise any saturated or olefinic halohydrocarbon wherein all of the hydrogen atoms are substituted onto one carbon, and all of the halogen atoms are substituted onto the other carbon. Preferably, the halohydrocarbon comprises vinylidene chloride and/or 1,1,1-trichloroethane. Additional halohydrocarbon compounds readily catalytically hydrofluorinated to vinylidene fluoride include, for example, 1-chloroethylene, 1,2,2-trichloroethylene, tetrachloroethylene, 1-chloro-1-fluoroethylene, 1,1-dichloro-1-fluoroethane, 1-chloro-1,1-difluoroethane, and the like. 1-Chloro-1-fluoroethylene, 1,1-dichloro-1-fluoroethane and 1-chloro-1,1-difluoroethane may be generated as intermediates in the hydrofluorination of 1,1,1-trichloroethane or vinylidene chloride.

The reaction is generally carried out in the presence of a suitable heterogeneous catalyst. The catalyst advantageously comprises a metal fluoride, for example,  $\text{AlF}_3$ ,  $\text{CrF}_3$ ,  $\text{FeF}_3$ ,  $\text{SbF}_5$ ,  $\text{NiF}_2$ ,  $\text{BF}_3$ ,  $\text{SnF}_4$ , and combinations thereof. Other suitable catalysts for use in the process include metal oxides or metal chlorides which are converted to the corresponding metal fluorides upon activation with hydrogen fluoride. Thus, included in the catalysts which may be used in the herein process are compounds which may be converted to metal fluorides at the herein described reaction conditions. Such catalysts include, by way of example, and not by limitation,  $\text{FeCl}_3$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{CoCl}_2$ ,  $\text{CoO}$ ,  $\text{CrCl}_3$ ,  $\text{Cr}_2\text{O}_3$ , and the like. The catalyst may be used directly, or may be carried on an appropriate catalyst support, such as  $\gamma$ -aluminum oxide. Such supported catalysts may be employed, for example, in the form of pellets or granules.

While the ratio of hydrogen fluoride to  $\text{CH}_n\text{CX}_m$  halohydrocarbon advantageously fed to the reaction zone is from about 1:1 to about 10:1, the amount of hydrogen fluoride delivered to the reaction zone may, in some circumstances, be satisfactorily reduced to zero, as sufficient hydrogen fluoride may be generated to sustain the hydrofluorination of the halohydrocarbon feed by the simultaneous dehydrofluorination of 1,1,1-trifluoroethane. The amount of hydrogen fluoride required to sustain the production of vinylidene fluoride at satisfactory levels should therefore necessarily take into account the amount of hydrogen fluoride generated in situ as a dehydrofluorination product. For example, two moles of 1,1,1-trifluoroethane will generate sufficient hydrogen fluoride to convert one mole of vinylidene chloride to vinylidene fluoride. In some circumstances, sufficient 1,1,1-trifluoroethane may be supplied to the reaction zone from an independent source such that the hydrogen fluoride requirement for sustaining the hydrofluorination reaction may be satisfied by the hydrogen fluoride formed in situ by the

dehydrofluorination of 1,1,1-trifluoroethane. In such circumstances a separate hydrogen fluoride feed is unnecessary. On the other hand, if the 1,1,1-trifluoroethane introduced into the reaction zone is not sourced from outside the reaction system, but rather merely comprises a 1,1,1-trifluoroethane recycle feed, hydrogen fluoride from an independent source must be supplied to sustain the hydrofluorination reaction for extended periods.

An oxidizing agent may optionally be introduced into the reaction zone to insure that the catalyst remains free of carbonaceous deposits or "coke". Thus, an oxidizing gas may be introduced into the reactor to accelerate the combustion of any carbonaceous deposits which may accumulate on the catalyst surface as a result of the burning of organic reactants. Such oxidizing gases may include, for example,  $\text{O}_2$  and/or  $\text{CO}_2$ . The oxidizing gas is advantageously combined with the feed halohydrocarbon as it is fed to the reaction zone. Where  $\text{O}_2$  is used as the oxidizing agent, the ratio of  $\text{O}_2$  to the halohydrocarbon may vary from about 0 to about 20 mol%, preferably from about 5 to about 10 mold. Where  $\text{CO}_2$  is used as the oxidizing gas, the ratio of  $\text{CO}_2$  to halohydrocarbon may vary from about 0 to about 200 mol%, preferably from about 50 to about 100 mol%.

The process of the invention may be carried out as a batch, semi-continuous, or continuous process. Preferably, the process is conducted in a continuous fashion comprising continuously feeding hydrogen fluoride and the halohydrocarbon to the reaction zone to form a vapor phase reaction mixture thereof. Hydrogen fluoride and the halohydrocarbon are continuously reacted in the presence of the heterogeneous catalyst. A product mixture comprising vinylidene fluoride and 1,1,1-trifluoroethane is continuously withdrawn from the reaction zone. After separation of vinylidene fluoride, at least a portion of the 1,1,1-trifluoroethane is recycled back to the reaction zone.

Any amount of 1,1,1-trifluoroethane may be recycled back to the reaction mixture. Preferably, substantially all the 1,1,1-trifluoroethane by-product of the gas phase hydrofluorination reaction is recycled back to the reaction zone, to maximize efficiency. When 1,1,1-trifluoroethane from an independent source is utilized, the amount added to the reaction mixture may vary considerably. Even the smallest amount will provide a benefit. Amounts of 1,1,1-trifluoroethane in excess of 70 mol%, based on the combined amount of hydrogen fluoride and the feed halohydrocarbon, are generally not preferred since the other components of the reaction mixture may begin to become too dilute.

In a typical continuous operation, hydrogen fluoride and the feed halohydrocarbon are passed through a tubular reactor loaded with a hydrogen

fluoride-activated catalyst. The reaction products, being predominantly a mixture of vinylidene fluoride and 1,1,1-trifluoroethane, are continuously removed from the reactor as gas phase products, and passed to a suitable scrubbing tower for removal of HCl and HF by the action of a countercurrent alkaline stream. The alkaline stream may comprise, for example, 16% potassium hydroxide solution. Other aqueous hydroxides such as sodium hydroxide or calcium hydroxide may be advantageously utilized. The scrubbed product is then passed to a drying tower which is packed with a suitable drying agent, e.g. anhydrous calcium sulfate.

Vinylidene fluoride is readily separated from the other components of the reactor effluent gas by conventional techniques such as distillation, and the like, preferably after removal of hydrogen fluoride and hydrogen chloride. The effluent gas, comprising predominantly vinylidene fluoride and 1,1,1-trifluoroethane, the feed halohydrocarbon, minor amounts of intermediates such as chlorofluoroethylene, 1,1-dichloro-1-fluoroethane, 1-chloro-1,1-difluoroethane, and the like, and also the oxidizing gas, is subjected to a separation process which preferentially separates vinylidene fluoride. Separation is most advantageously achieved by distilling vinylidene fluoride, which has a boiling point of  $-86^{\circ}\text{C}$ , from the product mixture.

Separation of vinylidene fluoride may be accomplished in a conventional distillation column which is operated, for example, at a temperature and pressure at the column top of about  $-4^{\circ}\text{C}$  and 285 PSIG, respectively, and a bottom temperature and pressure of about  $38^{\circ}\text{C}$  and 280 PSIG, respectively. Under these conditions, vinylidene fluoride is readily separated from 1,1,1-trifluoroethane, which has a boiling point of  $-48^{\circ}\text{C}$ , and from the various feed halohydrocarbons and reaction intermediates, which boil at temperatures substantially higher than the  $-86^{\circ}\text{C}$  boiling point of vinylidene fluoride. At least a portion of the distillation bottom product, which comprises 1,1,1-trifluoroethane, the feed halohydrocarbon and hydrofluorination intermediates, is advantageously recycled to the reaction mixture. While the oxidizing gas is taken overhead with the vinylidene fluoride, the two may be thereafter separated by simple distillation.

The materials of construction of the reactor for use in the present process should possess the necessary structural and physical characteristics to withstand the reaction conditions.

The present invention is illustrated in more detail by reference to the following non-limiting examples.

#### Comparative Example 1

A 7.5 wt.%  $\text{FeF}_3/\text{AlF}_3$  catalyst was prepared as follows and utilized for the conversion of vinylidene chloride to vinylidene fluoride.

Alumina (200 g, 1.96 mol) was added portionwise to a magnetically-stirred solution of 52% by weight of aqueous HF (500 ml, 15 mol). Addition of alumina was controlled to keep the temperature of the reaction mixture between  $40^{\circ}$  and  $45^{\circ}\text{C}$ . The addition took seven hours. The resulting milky suspension was left at room temperature overnight. Upon standing, a fine powder (presumably  $\text{AlF}_3 \cdot 9\text{H}_2\text{O}$ ) precipitated. A solution of 37.5 g  $\text{FeCl}_3$  (0.23 mol) in 20 ml  $\text{H}_2\text{O}$  was added gradually to the mechanically-stirred aqueous  $\text{AlF}_3$  mixture. The solution turned a light violet color. The stirring was continued for four hours and the mixture was left to settle at room temperature overnight. The product precipitate was filtered and washed with acetone several times until the filtrate was acid free. The solid obtained was dried in air at room temperature and was heated at  $100^{\circ}\text{C}$  for 2 hours,  $150^{\circ}\text{C}$  for 2 hours and finally at  $175^{\circ}\text{C}$  for 16 hours. The resulting  $\text{FeF}_3/\text{AlF}_3$  (7.5 wt.%  $\text{FeF}_3/\text{AlF}_3$ ) catalyst was ground using a mortar and pestle, and was sieved. The 60 to 100 mesh particles were collected and used to fill a nickel, fixed bed tubular reactor (1 inch outside diameter x 12 inches). The bed was heated using a single zone furnace. The catalyst was gradually heated to  $650^{\circ}\text{C}$  at the rate of  $100^{\circ}\text{C}$  per hour, using air fed to the reactor at the rate of  $20\text{ cm}^3/\text{min}$ . The catalyst was maintained at this temperature and air flow for two and one half days. The temperature of the reactor was then lowered to  $550^{\circ}\text{C}$ , and hydrogen fluoride at the rate of 0.03 g/min. and  $\text{N}_2$  at the rate of 20 ml/min. were passed over the catalyst for 18 hours. The temperature was raised to  $650^{\circ}\text{C}$  and a mixture of 15 mol% vinylidene chloride, 54 mol% hydrogen fluoride, 1 mol%  $\text{O}_2$  and 30 mol%  $\text{N}_2$  were fed to the reactor through valves located at the reactor top. The product was withdrawn, and after scrubbing HCl and excess HF with a 16% KOH solution, the scrubbed product was dried with anhydrous  $\text{CaSO}_4$ . Analysis of the product by gas chromatography indicated a 34 mol% conversion of vinylidene chloride. Selectivity for vinylidene fluoride was 15 mol%.

#### Example 1

The procedure of Comparative Example 1 was repeated, except that the  $\text{N}_2$  was replaced with a like amount of 1,1,1-trifluoroethane. Conversion of vinylidene chloride increased to 100 mol%. Selec-

tivity for vinylidene fluoride was calculated as net vinylidene fluoride selectivity, by subtracting from the product the amount of 1,1,1-trifluoroethane which was added in the reactor feed. The net vinylidene fluoride selectivity was 23 mol%. The balance of the product distribution was as follows: 1,1,1-trifluoroethane, 73 mol%; 1,1-difluoro-1-chloroethane, 3 mol%; and 1-chloro-1-fluoroethylene, 1 mol%.

It is apparent from a study of Comparative Example 1 and Example 1 that fluorination of vinylidene chloride increased from 32 mol% to 91 mol%, upon substitution of 1,1,1-trifluoroethane for the diluent (100% fluorination being defined as complete conversion of vinylidene chloride to 1,1,1-trifluoroethane).

The mass balance in the reactor was computed by dividing the measured flow rate of material from the reactor by the measured flow rate of material into the reactor. The mass balance for Comparative Example 1, using N<sub>2</sub> as the diluent, was 87%. Substituting 1,1,1-trifluoroethane as the diluent in Example 1 resulted in a mass balance of 95%. This means that the amount of product lost as coke on the catalyst was reduced from 13% to 5%, when 1,1,1-trifluoroethane was substituted for N<sub>2</sub> as the reaction diluent.

#### Comparative Example 2

A 6.4 wt.% NiCl<sub>2</sub>/AlF<sub>3</sub> catalyst was prepared as follows and utilized in the conversion of vinylidene chloride to vinylidene fluoride.

NiCl<sub>2</sub> (29.94 grams in 150 ml of water was added to precipitated AlF<sub>3</sub> from aqueous hydrogen fluoride (as described in Comparative Example 1). After drying and sieving the catalyst, 20 grams of the 60-100 mesh size particles were loaded into the same reactor as used in Comparative Example 1. The catalyst was air activated for two days at 650°C, using air fed to the reactor at the rate of 20 cm<sup>3</sup>/min. The catalyst was then activated by hydrogen fluoride fed at the rate of 0.03 g/min. for 18 hours at 550°C. A mixture of 1,1,1-trichloroethane, (10 mol%), HF (77 mol%), O<sub>2</sub> (2 mol%), N<sub>2</sub> (8 mol%) and BF<sub>3</sub> (3 mol%) was fed from the top of the reactor at 550°C. After removing HF and HCl, and drying the product as previously described in Comparative Example 1, analysis of the product gas by gas chromatography indicated 96 mol% conversion of 1,1,1-trichloroethane, with the following product distribution: 7 mol% vinylidene fluoride; 34 mol% vinylidene chloride; 17 mol% 1-chloro-1-fluoroethylene; 34 mol% 1,1,1-trifluoroethane; 4 mol% 1-chloro-1,1-difluoroethane; and 4 mol% 1-fluoro-1,1-dichloroethane.

#### Example 2

Comparative Example 2 is repeated except that the hydrogen fluoride feed was reduced, and 1,1,1-trifluoroethane was added to the reaction mixture as a diluent. The composition of the feed was as follows: 12 mol% 1,1,1-trichloroethane; 49 mol% HF; 3 mol% O<sub>2</sub>; 10 mol% N<sub>2</sub>; 4 mol% BF<sub>3</sub>; and 22 mol% 1,1,1-trifluoroethane. The conversion of 1,1,1-trifluoroethane achieved was 99 mol%. The net selectivity for vinylidene fluoride was 23 mol%, with the remaining product distribution comprising 20 mol% vinylidene chloride, 4 mol% 1-chloro-1-fluoroethylene, 50 mol% 1,1,1-trifluoroethane, 1 mol% 1-chloro-1,1-difluoroethane, and 2 mol% 1,1-dichloro-1-fluoroethane.

From a consideration of Example 2 and Comparative Example 2, it may be appreciated that upon addition of 1,1,1-trifluoroethane as a reaction diluent, total fluorination of 1,1,1-trichloroethane increased from 47 mol% to 67 mol%, despite the fact that the hydrogen fluoride/1,1,1-trichloroethane molar ratio was decreased from 7.7:1 to 4.1:1. The calculated loss of product as catalyst coke decreased from 90% to 49%.

#### Comparative Example 3

A catalyst comprising 3.35 wt.% SbF<sub>5</sub> and 6.1 wt.% NiF<sub>2</sub>/AlF<sub>3</sub> was prepared as follows and utilized in the conversion of vinylidene chloride to vinylidene fluoride.

A solution of NiCl<sub>2</sub> (29.94 g, 0.23 mol) in 50 ml of water was added to AlF<sub>3</sub> precipitated from Al<sub>2</sub>O<sub>3</sub> (200 g) and hydrogen fluoride (500 ml, 50%) according to Comparative Example 1. The NiCl<sub>2</sub> solution was added to the AlF<sub>3</sub> with continuous stirring. SbCl<sub>5</sub> (22.4 g, 0.075 mol) was added portionwise over a three hour period. The resulting mixture was left standing overnight to precipitate. The mixture was filtered and acetone-washed. The filter cake was collected, air dried, then heated in an oven at 100°C for 2 hours, at 150°C for 2 hours and finally at 175°C for 18 hours. The resulting catalyst was ground, sieved, and 34.7 grams of the 60-80 mesh particles were collected and loaded into the reactor as described previously in Comparative Example 1. A mixture of 9.5 mol% 1,1,1-trichloroethane, 39 mol% hydrogen fluoride, 0.5 mol% O<sub>2</sub> and 51 mol% N<sub>2</sub> was fed into the reactor. Conversion of 1,1,1-trichloroethane was 100%. The product distribution was as follows: vinylidene fluoride, 2 mol%; vinylidene chloride, 79 mol%; 1-chloro-1-fluoroethylene, 14 mol%, 1,1,1-trifluoroethane, 2 mol%; other products, 3 mol%.

### Example 3

Comparative Example 3 was repeated, except that the reactor feed comprised the following mixture: 13 mol% 1,1,1-trichloroethane; 49 mol% HF; 3 mol% O<sub>2</sub>; 11 mol% N<sub>2</sub>; and 24 mol% 1,1,1-trifluoroethane. Conversion of 1,1,1-trichloroethane was 94 mol%. The net selectivity for vinylidene fluoride was 48% mol. The remaining product distribution was as follows: 1,1,1-trifluoroethane, 51 mol%; and 1-chloro-1,1-difluoroethane, 1 mol%.

From a comparison of Comparative Example 3 with Example 3, it is observed that the total fluorination of 1,1,1-trichloroethane increased from 8 mold to 79 mol% upon the addition of 1,1,1-trifluoroethane as a diluent.

The present invention may be embodied in other specific forms without departing from the spirit or essential attributes thereof and, accordingly, reference should be made to the appended claims, rather than to the foregoing specification, as indicating the scope of the invention.

### Claims

1. A process for producing vinylidene fluoride comprising:  
forming a vapor phase reaction mixture comprising hydrogen fluoride and at least one halohydrocarbon of the formula CH<sub>n</sub>CX<sub>m</sub> wherein n and m are 2 or 3 and each X is independently selected from the group of fluorine, chlorine, bromine and iodine;  
adding 1,1,1-trifluoroethane to the vapor phase reaction mixture as a diluent;  
reacting the hydrogen fluoride and halohydrocarbon in a reaction zone in the presence of a heterogeneous catalyst; and  
obtaining vinylidene fluoride as a reaction product.

2. A process according to claim 1 wherein 1,1,1-trifluoroethane is produced as a reaction product, and at least a portion thereof is added back to the reaction mixture as a diluent.

3. A process according to claim 1 wherein the halohydrocarbon is selected from the group of vinylidene chloride, 1,1,1-trichloroethane and mixtures thereof.

4. A process according to claim 1 wherein the reaction temperature in the reaction zone is from about 400°C to about 650°C.

5. A process according to claim 4 wherein the reaction temperature in the reaction zone is from about 550°C to about 625°C.

6. A process according to claim 1 wherein the halohydrocarbon and hydrogen fluoride are in contact in the reaction zone for a period of time from about 1 second to about 20 seconds.

7. A process according to claim 6 wherein the halohydrocarbon and hydrogen fluoride are in contact in the reaction zone for a period of time from about 5 seconds to about 20 seconds.

8. A process according to claim 1 wherein the vapor phase reaction mixture is formed by feeding hydrogen fluoride and the halohydrocarbon to the reaction zone in a molar feed ratio of from about 0:1 to about 10:1.

9. A process according to claim 8 wherein the molar feed ratio is from about 4:1 to about 1:1.

10. A process according to claim 1 wherein the catalyst is selected from the group of AlF<sub>3</sub>, CrF<sub>3</sub>, FeF<sub>3</sub>, SbF<sub>5</sub>, NiF<sub>2</sub>, BF<sub>3</sub>, SnF<sub>4</sub> and combinations thereof.

11. A process according to claim 2 wherein the halohydrocarbon is selected from the group of vinylidene chloride and 1,1,1-trichloroethane, and combinations thereof.

12. A process according to claim 11 wherein:  
the reaction temperature is from about 400°C to about 650°C;

hydrogen fluoride and the halohydrocarbon are fed to the reaction zone in a molar feed ratio of from about 0:1 to about 10:1, and are in contact in the reaction zone for a period of time from about 1 second to about 20 seconds; and

the heterogeneous catalyst is selected from the group of AlF<sub>3</sub>, CrF<sub>3</sub>, FeF<sub>3</sub>, SbF<sub>5</sub>, NiF<sub>2</sub>, BF<sub>3</sub>, SnF<sub>4</sub> and combinations thereof.

13. A process according to claim 12 wherein:  
the reaction temperature is from about 550°C to about 625°C; and

hydrogen fluoride and the halohydrocarbon are fed to the reaction zone in a molar feed ratio of from about 4:1 to about 1:1, and are in contact in the reaction zone for a period of time from about 5 seconds to about 20 seconds.

14. A continuous process for the production of vinylidene fluoride comprising:

continuously feeding to a reaction zone at least one halohydrocarbon of the formula CH<sub>n</sub>CX<sub>m</sub> wherein n and m are 2 or 3 and each X is independently selected from the group of fluorine, chlorine, bromine and iodine;

continuously reacting the halohydrocarbon with hydrogen fluoride in the vapor phase in the presence of a heterogeneous catalyst in the reaction zone; and

continuously withdrawing from the reaction zone a product mixture comprising vinylidene fluoride and 1,1,1-trifluoroethane, and recycling at least a portion of the 1,1,1-trifluoroethane to the reaction zone.

15. A process according to claim 14 wherein vinylidene fluoride is distilled from the product mixture and at least a portion of the distillation bottom product is recycled to the reaction zone.

16. A process according to claim 14 wherein

the halohydrocarbon is selected from the group of vinylidene chloride and 1,1,1-trichloroethane, and combinations thereof.

17. A process according to claim 14 wherein the temperature in the reaction zone is from about 400 °C to about 650 °C. 5

18. A process according to claim 17 wherein the temperature in the reaction zone is from about 550 °C to about 625 °C.

19. A process according to claim 14 wherein the halohydrocarbon and hydrogen fluoride are in contact in the reaction zone for a period of time from about 1 second to about 20 seconds. 10

20. A process according to claim 19 wherein the halohydrocarbon and hydrogen fluoride are in contact in the reaction zone for a period of time from about 5 seconds to about 20 seconds. 15

21. A process according to claim 14 wherein the hydrogen fluoride and halohydrocarbon are continuously fed to the reaction zone in a molar feed ratio of from about 0:1 to about 10:1. 20

22. A process according to claim 21 wherein the molar feed ratio is from about 4:1 to about 1:1.

23. A process according to claim 14 wherein the catalyst is selected from the group of  $\text{AlF}_3$ ,  $\text{CrF}_3$ ,  $\text{FeF}_3$ ,  $\text{SbF}_5$ ,  $\text{NiF}_2$ ,  $\text{BF}_3$ ,  $\text{SnF}_4$ , and combinations thereof. 25

24. A process according to claim 15 wherein: the reaction temperature is from about 400 °C to about 650 °C; 30  
hydrogen fluoride and the halohydrocarbon are fed to the reaction zone in a molar feed ratio of from about 0:1 to about 10:1, and are in contact in the reaction zone for a period of time from about 1 second to about 20 seconds; and 35  
the heterogeneous catalyst is selected from the group of  $\text{AlF}_3$ ,  $\text{CrF}_3$ ,  $\text{FeF}_3$ ,  $\text{SbF}_5$ ,  $\text{NiF}_2$ ,  $\text{BF}_3$ ,  $\text{SnF}_4$  and combinations thereof.

25. A process according to claim 24 wherein: the reaction temperature is from about 550 °C to about 625 °C; and 40  
hydrogen fluoride and the halohydrocarbon are fed to the reaction zone in a molar feed ratio of from about 4:1 to about 1:1, and are in contact in the reaction zone for a period of time from about 5 45  
seconds to about 20 seconds.
